

strtoull(std::string_view)

1. Implement a C++ program that converts a string to float.

```
std::string number("67.563");  
auto converted { strtoull(number) };
```

- Make sure that you the type of the variable `converted` is `float` when the function returns.
- Also, show error if the string is invalid (i.e., `"12sd2"` is an invalid string because it doesn't have all elements that are numbers) and stop execution.
